SMT Series 9000 Ranging Modules

SensComp's Ranging Modules provide the drive electronics for SensComp Series 9000 Transducers

Features

Accurate Sonar Ranging from 12 inches to 18 feet
Drives a 45 kHz Series 9000 Piezoelectric Transducer
Without an Additional Interface
Operates from a Single Power Supply Source
Accurate Clock Output Provided for External Use
Selective Echo Exclusion
TTL Compatible
Multiple Measurement Capability
Integrated Transducer Cable
Variable Gain Control Potentiometer

Part No.

PID# 615085 – SMT Series 9000 Ranging Module
PID# 615086 – SMT Series 9000E Ranging Module,
Enhanced (Includes Pull-up Resistors and a
Cycle Oscillator for Repetitive Operation)
PID# 615087 – SMT Series 9000NC Ranging Module without
Connector (J1)

Specifications

PID#615085 Shown

Description

The SMT Series 9000 is an economical sonar ranging module that can drive SensComp's Series 9000 Piezoelectric Transducer. This module, with a simple interface, is able to measure distances from 12 inches to 18 feet. The typical accuracy is ±1% of the reading over the entire range.

This module has an external blanking input that allows selective echo exclusion for operation on a multiple-echo mode. The module is able to differentiate echoes from objects that are only three inches apart. The digitally controlled gain and variable bandwidth amplifier minimizes noise and side-lobe detection in sonar applications.

The module has an accurate ceramic resonator controlled 384 kHz time base generator. An output based on the 384 kHz time base is provided for external use. The sonar transmit output is 16 cycles at a frequency of 45 kHz.

The Series 9000 module operates over a DC power supply range from 4.5 volts to 6.8 volts (5 volts nominal) and is characterized for operation from 0° C to 70° C.

Absolute Maximum Ratings over Operating Free-Air Temperature Range

Voltage from any pin to ground (see Note 1)	7 VDC
Voltage from any pin except XDCR to V _{CC} (see Note 1)	
Operating free-air temperature range	
Storage temperature range	

NOTE 1: The XDCR pin may be driven from -1 volt to 400 volts typical with respect to ground.

Recommended Operating Conditions

		MIN	MAX	UNIT
Supply Voltage, Vcc		4.5	6.8	V
High-level Input Voltage, VIH	BLNK, BINH, INIT	2.1		V
Low-level Input Voltage, VIL	BLNK, BINH, INIT		0.6	V
ECHO and OSC Output Voltage	OSC Output Voltage		6.8	V
Delay Time, Power Up to INIT High		5	ms	
Recycle Period		80		ms
Operating Free-Air Temperature, T _A		0	70	°C

Electrical Characteristics over Recommended Ranges of Supply Voltage and Operating Free-Air Temperature

and Operating Free-Air Temperature								
PARAMETER		TEST COND.	MIN	TYP	MAX	UNIT		
Input Current	BLNK, BINH, INIT	V _I = 2.1 V			1	mA		
High-level Output Current, I _{OH}	ECHO, OSC	V _{OH} = 5.5V			100	μA		
Low-level Output Voltage, Vol.,	ECHO, OSC	I _{O L} = 1.6 mA			0.4	V		
Transducer Output Voltage (peak to peak)		T _A = 25° C		120		V		
No. of Cycles for XDCR Output to Reach 120V		C = 500 pF			7			
Internal Blanking Interval				2.38†		ms		
XMIT Drive Signal Duration				1.1†		ms		
Frequency During 16-Pulse	OSC Output			45†		kHz		
Transmit Period	XMIT Output			45†		kHz		
Frequency After 16-Pulse	OSC Output			83.3†		kHz		
Transmit Period	XMIT Output			0		kHz		
Supply Current, Icc	During Transmit Period				2000	mA		
	After Transmit Period				100	mA		

[†] These typical values apply for a 384 kHz ceramic resonator

Operation With SensComp Series 9000 Transducers

There are two basic modes of operation for the Series 9000 Sonar Ranging Modules: Single-echo mode and multiple-echo mode. The application of power (V_{CC}), the application of the initiate (INIT) input, and the resulting transmit output, and the use of the Blanking Inhibit (BINH) input are basically the same for either mode of operation. After applying power (V_{CC}) a minimum of 5 milliseconds must elapse before the INIT signal can be taken high. During this time, all internal circuitry is reset and the internal oscillator stabilizes. When INIT is raised to a high level, drive to the transducer (XDCR) output occurs. Sixteen pulses at 45 kHz, with a 0 to 120 volts peak to peak amplitude, will excite the transducer as transmission occurs. At the end of the 16 transmitted pulses, the sonar ranging module switches to the receive mode.

In order to eliminate ringing of the transducer from being detected as a return signal, the Receive (REC) input of the ranging control IC is inhibited by internal blanking for 2.38 milliseconds after the initiate signal. If a reduced blanking time is desired, then the BINH input can be taken high to end the blanking of the Receive input any time prior to internal blanking. This may be desirable to detect objects closer than 1.33 feet (corresponding to 2.38 milliseconds) and may be done if transducer damping is sufficient so that ringing is not detected as a return signal.

In the single-echo mode of operation (Figure 1), all that must be done next is to wait for the return of the transmitted signal, traveling at approximately 0.9 milliseconds per foot out and back. The returning signal is amplified and appears as a high logic level echo output. The time between INIT going high and the Echo (ECHO) output going high is proportional to the distance of the target from the transducer. If desired, the cycle can now be repeated by returning INIT to a low logic level and then taking it high when the next transmission is desired.

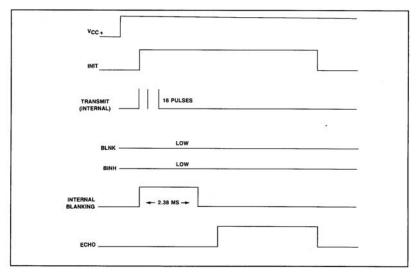

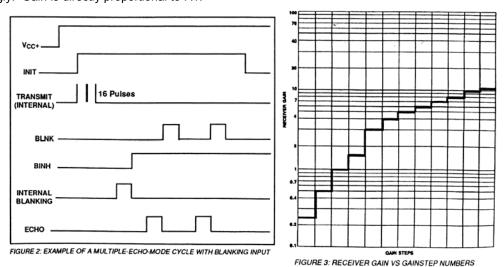

FIGURE 1: FXAMPLE OF A SINGLE-FCHO-MODE CYCLE WITHOUT BLANKING INPUT

If there is more than one target and a single transmission detects multiple echoes, then the cycle is slightly different (Figure 2). After receiving the first return signal which causes the ECHO output to go high, the Blanking (BLNK) input must be taken high then back low to reset the ECHO output for the next return signal. The blanking signal must be at least 0.44 milliseconds in duration to account for all 16 returning pulses from the first target and allow for internal delay times. This corresponds to the two targets being 3 inches apart.

During a cycle starting with INIT going high, the receiver amplifier gain is increased at discrete times (Figure 3) since the transmitted signal is attenuated with distance. At approximately 38 milliseconds, the maximum gain is attained. Although gain can be increased by varying R1 (see Component Layout), there is a limit to which the gain can be increased for reliable module operation. This will vary from application to application. The modules are "kitted" prior to their final test during manufacture. This is necessary because the desired gain distribution is much narrower than the module gain distribution if all were kitted with one value resistor. As kitted, these modules will perform satisfactorily in most applications. As a rule of thumb, the gain can be increased up to a factor of 4, if required, by increasing R1 correspondingly. Gain is directly proportional to R1.

Input/Output Schematic Notes:

The ECHO and OSC outputs are open collector NPN transistor outputs (Figure 4) requiring 4.7K ohm pull-up resistors between V_{CC} and the output.
